liftoffr

Read the Bitcoin Cycle Yourself

The nine weighted components behind the LiftOffr Score, what each one read at every cycle turn since 2013, and how to recompute the number without me.

No trigger prices. No allocations. No instructions.

Everything in here is checkable free at liftoffr.com

Your first cycle review

Use this guide to check the LiftOffr Score yourself: identify the data date, inspect the nine inputs, reproduce the weighted average, and examine historical outcomes. No signup or paid software is required. The five-step checklist is at **liftoffr.com/checklist**.

Start with one dated reading. Write down its source date, which components are available, and the total weight used. Then compare your calculation with **liftoffr.com/score**. If they differ, check dates, normalization and missing inputs before drawing a conclusion.

Work through it once and you'll be able to read any day's Score on your own.

The nine components, and what each one is worth

The Score is a weighted average of nine public indicators, normalised 0-100. The weights are fixed, published, and the only thing that turns nine readings into one number.

Component	Weight	What it measures
RHODL Ratio	20%	Where value sits between recently-moved and long-dormant coins
Puell Multiple	20%	Miner revenue against its own yearly average
Trolololo trend line	15%	Price against a long-run logarithmic regression
MVRV Z-Score	15%	Market value against realised value, in standard deviations
Pi Cycle Top	10%	The 111-day MA against twice the 350-day MA
2-Year MA Multiplier	5%	Price between its two-year mean and five times that mean
Reserve Risk	5%	Holder conviction against the reward for abandoning it
Woobull Top Cap	5%	Price as a fraction of a modelled long-run ceiling
RUPL / NUPL	5%	Aggregate net unrealized profit/loss relative to market cap

They sum to 100%. Nothing else feeds the number — not sentiment, not search interest, not anything proprietary.

The weights are design choices informed by fifteen years of cycle history.

The Phase Matrix

What each component read on the day of each cycle turn, normalised 0-100, from the same daily series the live number is built from.

Component	Wt	2013 top	2017 top	2021 top	2025 top	2015 bot	2018 bot	2022 bot
RHODL Ratio	20%	100	100	93	89	0	2	3
Puell Multiple	20%	99	100	76	95	0	0	17
Trololollo trend line	15%	100	100	100	86	0	4	0
MVRV Z-Score	15%	97	100	88	92	0	0	0
Pi Cycle Top	10%	95	100	58	71	0	17	11
2-Year MA Multiplier	5%	98	100	81	96	0	6	0
Reserve Risk	5%	96	100	91	99	0	7	0
Woobull Top Cap	5%	96	100	92	93	0	0	0
RUPL	5%	100	100	98	96	5	0	0

Read down a column to see what a cycle turn looked like across the whole model at once. Read across a row to see how one component has behaved over four tops and three bottoms.

The thing the columns show that no single indicator can. No component reads at its extreme at every turn. Pi Cycle read 100 in 2017 and 71 in 2025. Puell read 76 at the 2021 top against 99 in 2013. A reading that would have been decisive in one cycle was unremarkable in the next. That is the entire case for weighting nine of them instead of trusting one.

The six bands

Band	Range	What the record shows
Exit zone	85–100	Selected historical tops printed here; the band also persisted while price rose.
Warning	70–below 85	Has preceded exit-zone readings in past cycles.
Mid-cycle	50–below 70	The middle range of this scale.
Re-accumulation	30–below 50	Historically resolved upward more often than not over 180 days.
Accumulation	15–below 30	Among the lower readings in a cycle.
Deep accumulation	0–below 15	The lowest band this model produces.

Each band tells you which part of your written plan applies.

I am not printing today's Score here, because a number in a PDF is wrong by the time you read it. The live one is free, forever, at **liftoffr.com/score**.

The divisor rule — the part everyone gets wrong

Some days a source publishes no reading for a component. Pi Cycle alone has no published value on roughly 349 days of the 5,533-day source series, so any date you pick has a real chance of being one where something is missing.

A missing reading is excluded. It is never counted as a zero. When a 5% component does not report, you divide by 0.95, not by 1.00.

For example, eight weighted readings sum to 34.5 and the available weights sum to 0.95. The Score is 34.5 ÷ 0.95 = 36.3, rounded to one decimal place. Dividing by 1.00 would incorrectly treat the missing component as zero. Match the data date as well as the formula.

Recompute it yourself, in about ten minutes

Do this once and you never have to take my word for a number again.

1. Open **colintalkscrypto.com/cbbi** — the public daily data source. Free, no account.
2. Read off the nine component values. They are already normalised to 0-100.
3. Multiply each by its weight from the nine-component table earlier in this document.
4. Add the products.
5. Divide by the weight you actually used — 1.00 if all nine reported, less if any did not.
6. Compare against **liftoffr.com/score**.

You should land on the same number.

If you run it properly and get something materially different, tell me and I will fix it. That offer is the entire reason the weights are public, and it has been taken up and been correct at least once.

To check a past date instead of today, pick any row from the 64-crossing log at liftoffr.com/receipts and recompute that date. The same divisor rule applies.

What carries zero weight, and why

Three well-known indicators are deliberately not inputs. They are worth looking at. They are not part of the number, and confusing the two is how people end up unable to reproduce a figure they were told they could check.

CBBI is the *source*, not a component. The Score reads its nine component values from CBBI's public data. Including CBBI's own composite as a tenth input would count the same underlying readings twice.

The Fear & Greed Index measures how people feel; the Score measures what the chain and the price structure are doing. At the October 2025 top, Fear & Greed never reached Extreme Greed. A framework that required a sentiment extreme to confirm that top was waiting for a confirmation that never arrived.

Google Trends measures retail attention, which historically follows price rather than leading it, and its scale is relative to whatever window you chose — a "100" in one date range is not a "100" in another. There is no stable level to weight. At the October 2025 top it sat well below its 2021 levels.

How the exit zone played out in 2025

Between 16 November 2024 and 21 October 2025 the Score moved in and out of the exit zone six times:

```
16 Nov 2024   into exit zone     BTC $90,568
18 Feb 2025   back out           BTC $95,444
 8 May 2025   into exit zone     BTC $103,070
19 Jun 2025   back out           BTC $104,710
27 Jun 2025   into exit zone     BTC $107,091
21 Oct 2025   back out           BTC $108,700
```

Three entries, three exits, one top. The top came on 6 October 2025 at $124,824, inside the third entry, and the Score left the exit zone fifteen days later.

Any rule of the form "above X, do something" will cross back and forth around X. That is what thresholds do, which is why a written plan decides in advance what a crossing means to you.

All 64 crossings, with the 30-, 90- and 180-day outcome beside each, are at liftoffr.com/receipts. Free, no email required.

What this is for, then

A number that is the same every morning, computed the same way, published with its weights, that tells you where in a cycle you are, plus a dated record of every signal it has produced.

Ready to turn it into a written plan? The **Bear Market Buy Plan** gives you the buy tiers, the fallback rules and a sizing worksheet to build your own at whatever size you're working with. $29 once, at liftoffr.com/plan.

Either way, you keep everything in this document, the live number and the full record.
